point

1.

You train a learning algorithm, and find that it has unacceptably high error on the test set. You plot the learning curve, and obtain the figure below. Is the algorithm suffering from high bias, high variance, or neither?

- High bias
- High variance
- Neither

2.

## Suppose you have implemented regularized logistic regression

# Advice for Applying Machine Learning

Quiz, ~~to classify~~ what object is in an image (i.e., to do object

recognition). However, when you test your hypothesis on a new

set of images, you find that it makes unacceptably large

errors with its predictions on the new images. However, your

hypothesis performs **well** (has low error) on the

training set. Which of the following are promising steps to

take? Check all that apply.

- Try adding polynomial features.
- Get more training examples.
- Use fewer training examples.
- Try using a smaller set of features.

3.

Suppose you have implemented regularized logistic regression

to predict what items customers will purchase on a web

shopping site. However, when you test your hypothesis on a new

set of customers, you find that it makes unacceptably large

errors in its predictions. Furthermore, the hypothesis

performs **poorly** on the training set. Which of the

following might be promising steps to take? Check all that

apply.

- Try using a smaller set of features.
- Try adding polynomial features.
- Try to obtain and use additional features.
- Try increasing the regularization parameter  $\lambda$ .

4.

Which of the following statements are true? Check all that apply.

- Suppose you are training a logistic regression classifier using polynomial features and want to select what degree polynomial (denoted  $d$  in the lecture videos) to use. After training the classifier on the entire training set, you decide to use a subset of the training examples as a validation set. This will work just as well as having a validation set that is separate (disjoint) from the training set.
- Suppose you are using linear regression to predict housing prices, and your dataset comes sorted in order of increasing sizes of houses. It is then important to randomly shuffle the dataset before splitting it into training, validation and test sets, so that we don't have all the smallest houses going into the training set, and all the largest houses going into the test set.
- A typical split of a dataset into training, validation and test sets might be 60% training set, 20% validation set, and 20% test set.
- It is okay to use data from the test set to choose the regularization parameter  $\lambda$ , but not the model parameters ( $\theta$ ).

point

5.

Which of the following statements are true? Check all that apply.

- If a learning algorithm is suffering from high bias, only adding more training examples may **not** improve the test error significantly.
- A model with more parameters is more prone to overfitting and typically has higher variance.
- When debugging learning algorithms, it is useful to plot a learning curve to understand if there is a high bias or high variance problem.
- If a neural network has much lower training error than test error, then adding more layers will help bring the test error down because we can fit the test set better.
